

# Static Program Checking

## CEGAR-based Specification Inference

Automated Software Analysis Group, Institute of Theoretical Informatics

**Jun.-prof. Dr. Mana Taghdiri**

Thursday– July 17, 2014

# Syntactic summaries by abstract interpretation

- Summarizes the behavior of a procedure as a symbolic relationship between pre and post states
- Summaries are declarative formulas in a subset of Alloy
  - Doesn't include **quantifiers**
  - Doesn't include **set comprehension**
- Provides both an upper and a lower bound on the final values of fields, return value, and allocated objects

relational expr  $\subseteq$  field'/variable'  $\subseteq$  relational expr

- The result can sometimes be precise

field'/variable' = relational expr

# Evaluations

- To evaluate the quality of the generated summaries
  - Evaluate their accuracy
    - Check if they are sufficient to prove the underlying code correct
- Widening parameters
  - Max number of operators = 1300
  - Max number of allocations = 5
  - Max number of unions (before closure) = 3
  - Max number of procedure contexts = 5

# Accuracy evaluation

- Run on
  - Java linked list
  - An open-source graph library
- All summaries were generated in less than 3 seconds
  - Even for code containing 81 nested distinct method calls
- For each summary, check
  - $\text{Summary}(\text{proc}) \Rightarrow \text{spec}(\text{proc})$
  - Spec is the actual specification of code, already available
  - The check is done by kodkod, so only in a finite scope
- For 30 procedures
  - 13 had accurate summaries
  - 16 had relatively accurate summaries (sufficient to check major properties)
  - Only in 1 case there was a major loss of information in the summary

## Difficult case

- Remove element from linked list
  - Removes the first occurrence of a given element
  - Although the list is updated at most once, the update is done in the loop
  - So the loop modifies the next field – which is the one traversed in the loop
  - So the loop analysis doesn't stabilize by inferring closure, but widens to univ
  - The summary allows next and prev fields of all objects to change arbitrarily

# CEGAR

- CounterExample-Guided Abstraction Refinement

# Program verification

Does M satisfy property?

(property is the top-level spec to check)

# Monolithic program verification

Does M satisfy property?

(considering the code of  
M1 and M2)

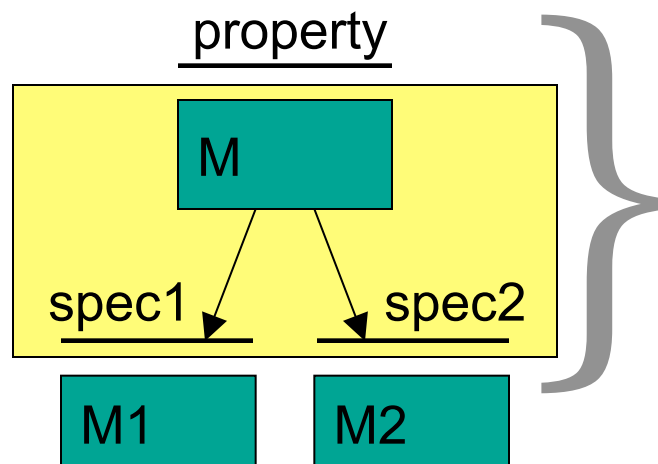

# Modular program verification

Does M satisfy property?

(assuming M1 satisfies spec1  
and M2 satisfies spec2)

# Automating modular verification

1. How to check the procedure?

Does M satisfy property?

(assuming M1 satisfies spec1  
and M2 satisfies spec2)

# Automating modular verification

1. How to check the procedure?

2. How to get the specs?

Does M satisfy property?

(assuming M1 satisfies spec1  
and M2 satisfies spec2)

## Tools we studied

- To check the program:
  - Jalloy
  - Jforge
  - ESC/Java
  
- To generate specs:
  - Houdini
  - Daikon
  - Static technique for relational specs
  
- These specs may be insufficient to prove detailed properties

## Goal: specs for structural properties

- Target **arbitrary data structure properties** of code
  - Constrain configuration of objects in the heap
  - Should handle aliasing, reachability, sets, maps, lists, etc.

```

some jw: this.jobsMap'.values'. |
  all x: jw.jobDetail'.listeners'.head'.*next' | some y: job.listeners.head'.*next' |
    (x.data' = y.data) and #(x.*next') = #(y.*next)
  
```

map

reachability

quantifiers

set cardinality

list

```

public void storeJob(JobDetail job, boolean replaceExisting, ...) {
  JobWrapper jw = new JobWrapper(job.clone());
  ...
  jobsmap.put(jw.key, jw);
  ...
}
  
```

## Insight

Inferring complete specs is infeasible in general

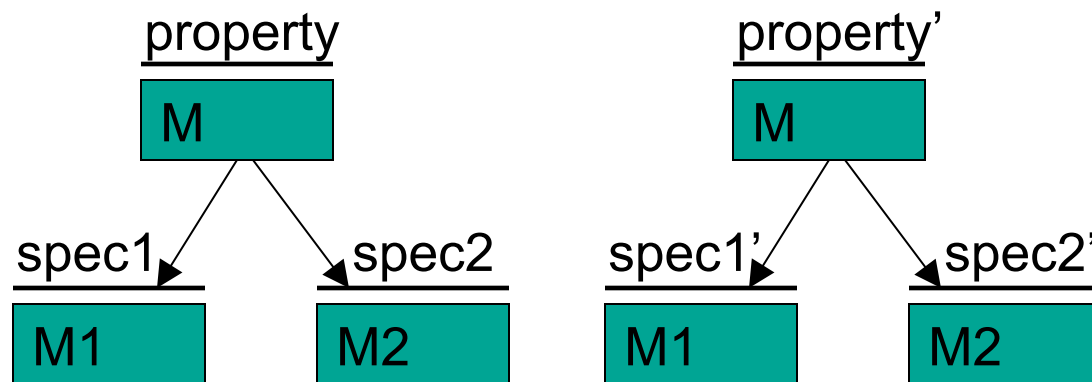

But, necessary specs need not be complete

# Insight

Inferring complete specs is infeasible in general

But, necessary specs need not be complete

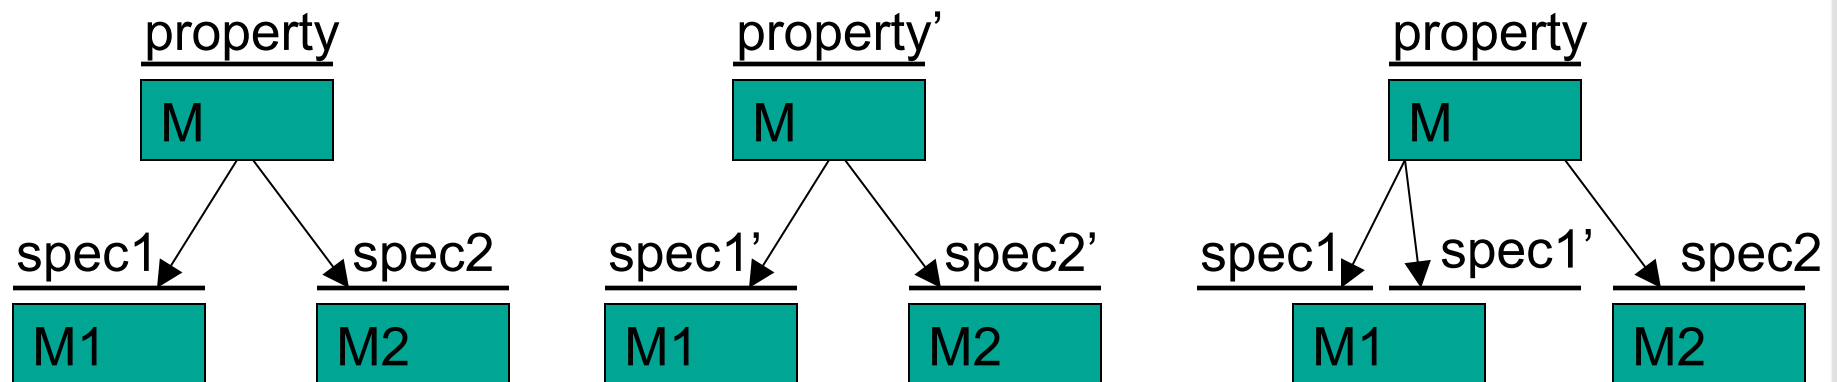

Necessary specs are **property dependent**

# Insight

Inferring complete specs is infeasible in general

But, necessary specs need not be complete

Necessary specs are **property dependent**

Necessary specs are **call site dependent**

## Example

```
class Job {
  JobList predecessors;
  JobList successors;
  int predsNum;
  int succsNum;
  int visitedPredsNum;
}
class JobList {
  Entry head;
}
class Entry {
  Job job;
  Entry next;
}
```

```
boolean scheduleJobs(JobList l) {
  boolean isAcyclic = true;
  l.init();
  Entry cur = l.head;
  while (cur != null) {
    Entry ready = findReady(cur);
    if (ready == null) {
      isAcyclic = false; break; }
    fixVisited(ready.job);
    swapJobs(ready, cur);
    cur = cur.next;
  } return isAcyclic;
}
```

# Example

```

class Job {
  JobList predecessors;
  JobList successors;
  int predsNum;
  int succsNum;
  int visitedPredsNum;
}
class JobList {
  Entry head;
}
class Entry {
  Job job;
  Entry next;
}
  
```

predecessors = [ j0, j2 ]  
 successors = [ j3 ]  
 predsNum = 2  
 succsNum = 1

# Example

```
boolean scheduleJobs(JobList l) {  
    boolean isAcyclic = true;  
    l.init();  
    Entry cur = l.head;  
    while (cur != null) {  
        Entry ready = findReady(cur);  
        if (ready == null) {  
            isAcyclic = false; break; }  
        fixVisited(ready.job);  
        swapJobs(ready, cur);  
        cur = cur.next;  
    } return isAcyclic;  
}
```

$l = [j_0, j_1, j_2, j_3]$

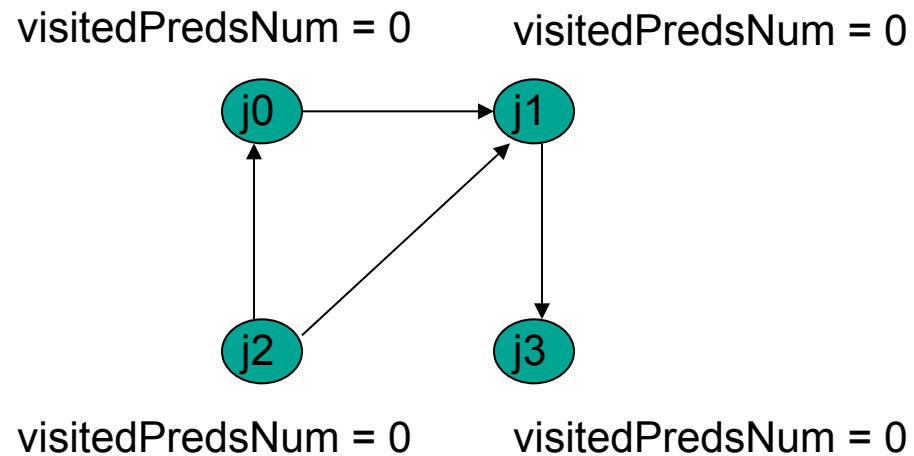

# Example

```

boolean scheduleJobs(JobList l) {
  boolean isAcyclic = true;
  l.init();
  Entry cur = l.head;
  while (cur != null) {
    Entry ready = findReady(cur);
    if (ready == null) {
      isAcyclic = false; break; }
    fixVisited(ready.job);
    swapJobs(ready, cur);
    cur = cur.next;
  } return isAcyclic;
}

```

$l = [j_0, j_1, j_2, j_3]$

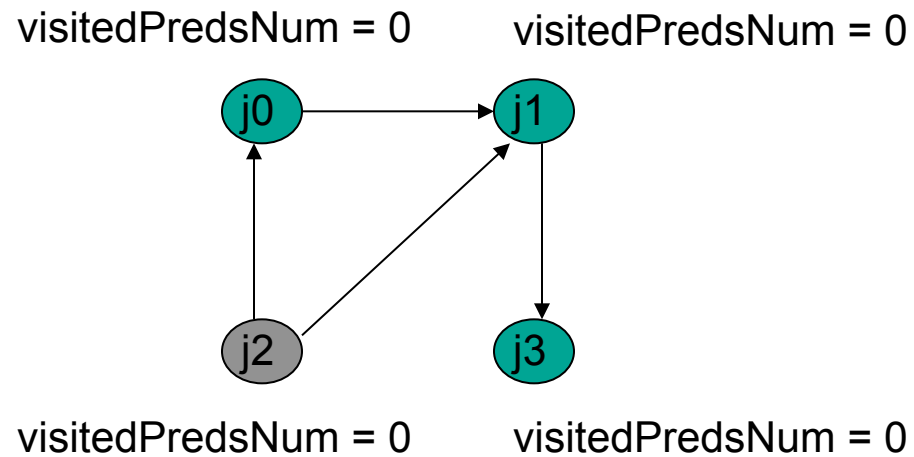

# Example

```

boolean scheduleJobs(JobList l) {
  boolean isAcyclic = true;
  l.init();
  Entry cur = l.head;
  while (cur != null) {
    Entry ready = findReady(cur);
    if (ready == null) {
      isAcyclic = false; break; }
    fixVisited(ready.job);
    swapJobs(ready, cur);
    cur = cur.next;
  } return isAcyclic;
}

```

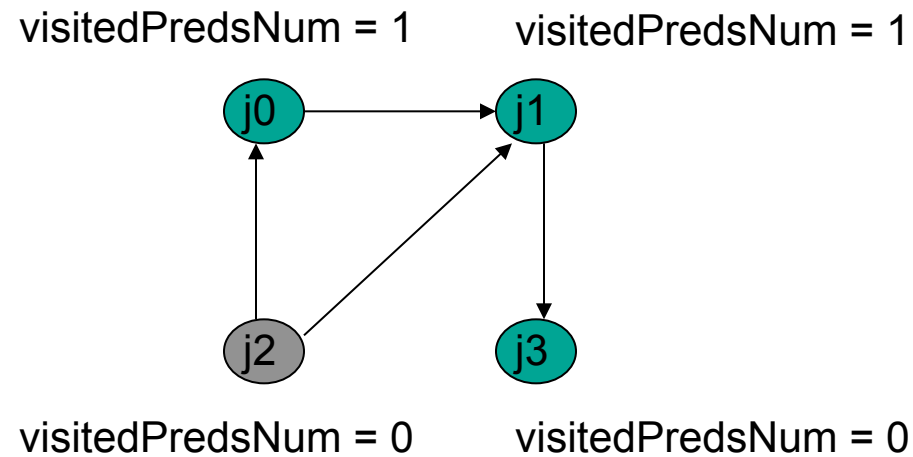

# Example

```

boolean scheduleJobs(JobList l) {
  boolean isAcyclic = true;
  l.init();
  Entry cur = l.head;
  while (cur != null) {
    Entry ready = findReady(cur);
    if (ready == null) {
      isAcyclic = false; break; }
    fixVisited(ready.job);
    swapJobs(ready, cur);
    cur = cur.next;
  } return isAcyclic;
}

```

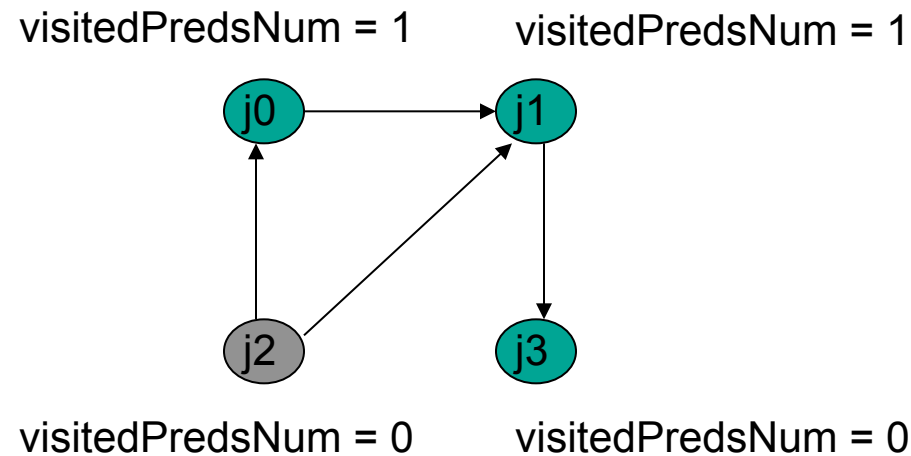

# Example

```

boolean scheduleJobs(JobList l) {
  boolean isAcyclic = true;
  l.init();
  Entry cur = l.head;
  while (cur != null) {
    Entry ready = findReady(cur);
    if (ready == null) {
      isAcyclic = false; break; }
    fixVisited(ready.job);
    swapJobs(ready, cur);
    cur = cur.next;
  } return isAcyclic;
}

```

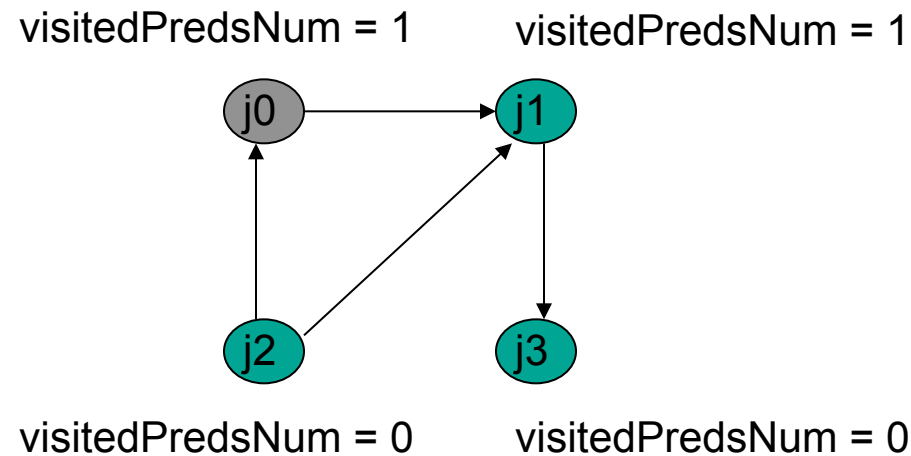

# Example

```

boolean scheduleJobs(JobList l) {
  boolean isAcyclic = true;
  l.init();
  Entry cur = l.head;
  while (cur != null) {
    Entry ready = findReady(cur);
    if (ready == null) {
      isAcyclic = false; break; }
    fixVisited(ready.job);
    swapJobs(ready, cur);
    cur = cur.next;
  } return isAcyclic;
}

```

# Example

```

class Job {
  JobList predecessors;
  JobList successors;
  int predsNum;
  int succsNum;
  int visitedPredsNum;
}

class JobList {
  Entry head;
}

class Entry {
  Job job;
  Entry next;
}

```

```

boolean scheduleJobs(JobList l) {
  boolean isAcyclic = true;
  l.init();
  Entry cur = l.head;
  while (cur != null) {
    Entry ready = findReady(cur);
    if (ready == null) {
      isAcyclic = false; break; }
    fixVisited(ready.job);
    swapJobs(ready, cur);
    cur = cur.next;
  } return isAcyclic;
}

```

jobs = head.\*next.job

Eventually schedules all jobs

(l.jobs' = l.jobs)

## Example – call site specs

Property can be checked  
with full specs for all call sites

(l.jobs' = l.jobs)

```

boolean scheduleJobs(JobList l) {
  boolean isAcyclic = true;
  l.init();
  Entry cur = l.head;
  while (cur != null) {
    Entry ready = findReady(cur);
    if (ready == null) {
      isAcyclic = false; break; }
    fixVisited(ready.job);
    swapJobs(ready, cur);
    cur = cur.next;
  } return isAcyclic;
}

```

**full spec:**

For all jobs, initializes its “visitedPredsNum” to 0

**full spec:**

Returns first node reachable from “cur” whose “visitedPredsNum” equals “predsNum”

**full spec:**

Increments “visitedPredsNum” of all successors of “e.job”

**full spec:**

Swaps the jobs of the given entries

# Example – call site specs

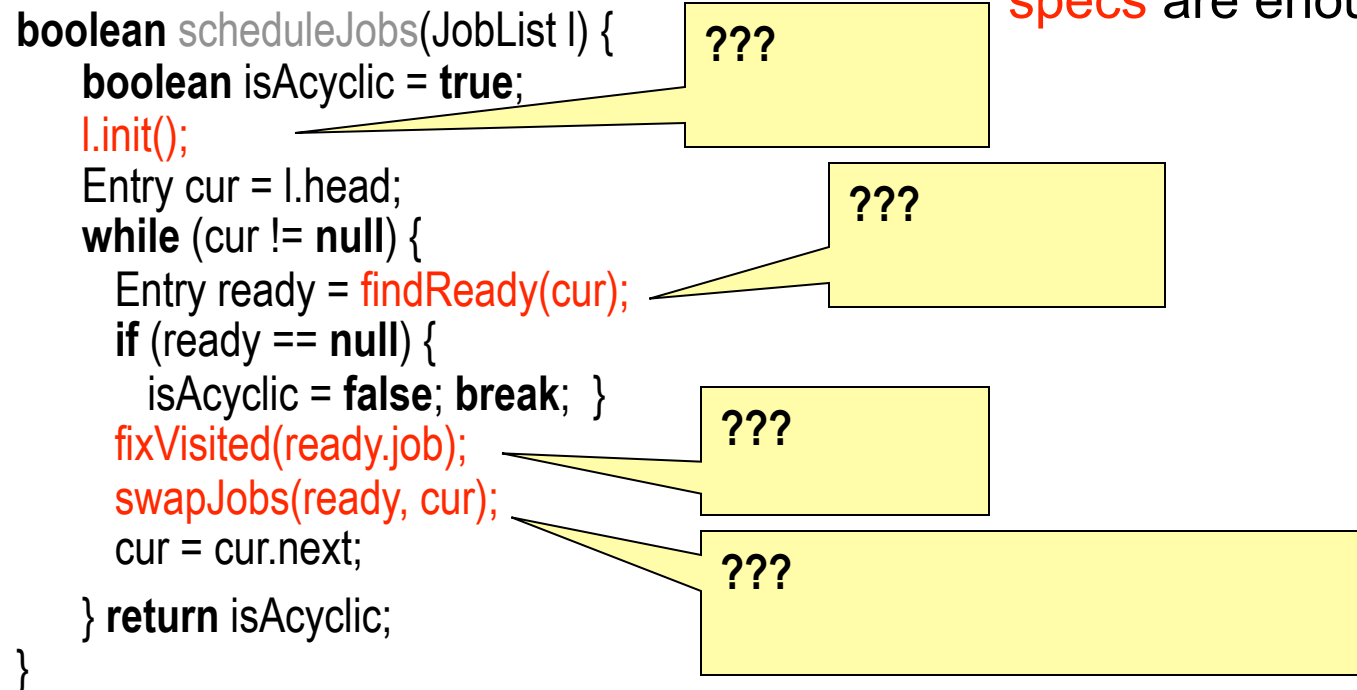

(l.jobs' = l.jobs)

Property can be checked with full specs for all call sites

But, for some calls, **partial specs** are enough

```

boolean scheduleJobs(JobList l) {
  boolean isAcyclic = true;
  l.init();
  Entry cur = l.head;
  while (cur != null) {
    Entry ready = findReady(cur);
    if (ready == null) {
      isAcyclic = false; break; }
    fixVisited(ready.job);
    swapJobs(ready, cur);
    cur = cur.next;
  } return isAcyclic;
}
  
```

The diagram illustrates call site specifications for the `scheduleJobs` method. Four yellow boxes, each containing '???' and connected to the code by lines, represent the specifications for the following call sites:

- `l.init();`
- `findReady(cur);`
- `fixVisited(ready.job);`
- `swapJobs(ready, cur);`

# Example – call site specs

(l.jobs' = l.jobs)

Property can be checked with full specs for all call sites

But, for some calls, **partial specs** are enough

```

boolean scheduleJobs(JobList l) {
  boolean isAcyclic = true;
  l.init();
  Entry cur = l.head;
  while (cur != null) {
    Entry ready = findReady(cur);
    if (ready == null) {
      isAcyclic = false; break; }
    fixVisited(ready.job);
    swapJobs(ready, cur);
    cur = cur.next;
  } return isAcyclic;
}
  
```

**partial spec:**  
jobs' = jobs

**partial spec:**  
\$ret  $\subseteq$  cur.\*next

**partial spec:**  
jobs' = jobs

**full spec:**  
Swaps the jobs of the given entries

# Example – call site specs

(l.jobs' = l.jobs)

Property can be checked with full specs for all call sites

But, for some calls, **partial specs** are enough

```

boolean scheduleJobs(JobList l) {
  boolean isAcyclic = true;
  l.init();
  Entry cur = l.head;
  while (cur != null) {
    Entry ready = findReady(cur);
    if (ready == null) {
      isAcyclic = false; break; }
    fixVisited(ready.job);
    swapJobs(ready, cur);
    cur = cur.next;
  } return isAcyclic;
}
  
```

**partial spec:**  
jobs' = jobs

**partial spec:**  
\$ret ⊆ cur.\*next

**partial spec:**  
jobs' = jobs

**full spec:**  
Swaps the jobs of the given entries

**We can infer these specs automatically**

# Approach: infer sufficient specs

## Benefits

- Analyzes only as much code as necessary
- Often performs better than inlining  
(reduces the analysis time of the example by factor of 15)
- Finds callees' bugs if relevant to the property

## Compromises

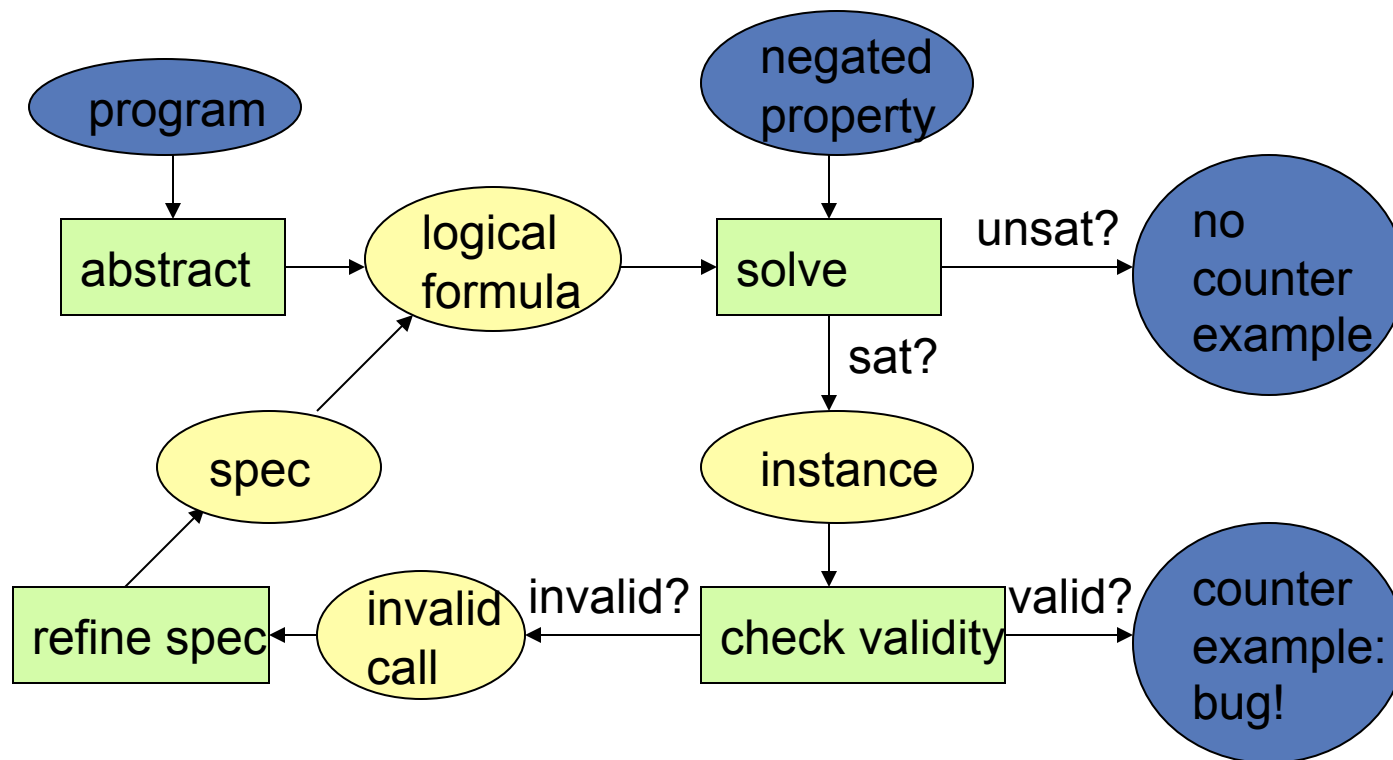

- Finitizes heap
- Finitizes loops/recursions

## Is a bug finder

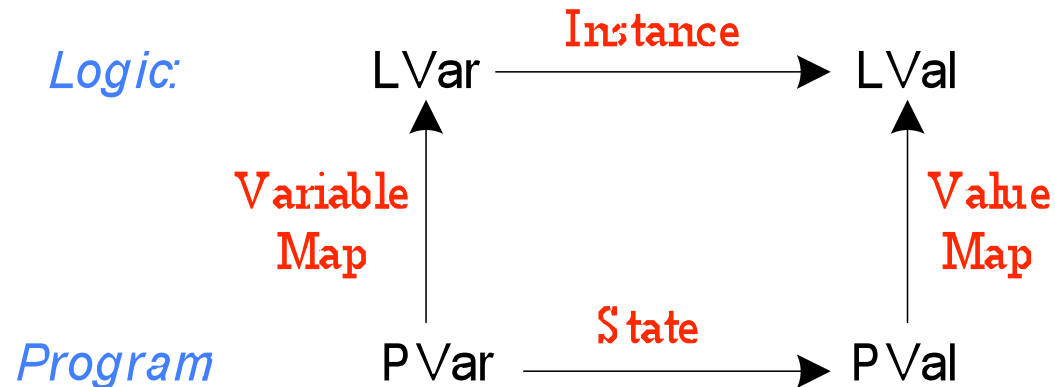

- Sound (no false negatives)
- Complete within bounds (bounded verification)

# Algorithmic overview: CEGAR

specification refinement

## Framework: domains

- Logic domain:
  - LVar (logical variables), LVal (logical values)
  
- Program domain:
  - PVar (program variables), PVal (program values)

## Framework: input functions

translate: Stmt  $\times$  VarMap  $\times$  ValueMap  $\rightarrow$  Formula  $\times$  VarMap

- Translates code to finite formula

solve: Formula  $\times$  Instance  $\rightarrow$   $\mathcal{P}$ Instance

$\text{solve}(f, i) = \{ i' \mid (i \subseteq i') \wedge (i' \in \llbracket f \rrbracket) \}$

- Solves a formula with respect to a partial instance

invalidate: Formula  $\times$  Instance  $\rightarrow$  Formula

$(\text{invalidate}(f, i) = g) \Rightarrow (\text{solve}(g, i) = \emptyset) \wedge (f \Rightarrow g)$

- Generates a formula that invalidates an instance

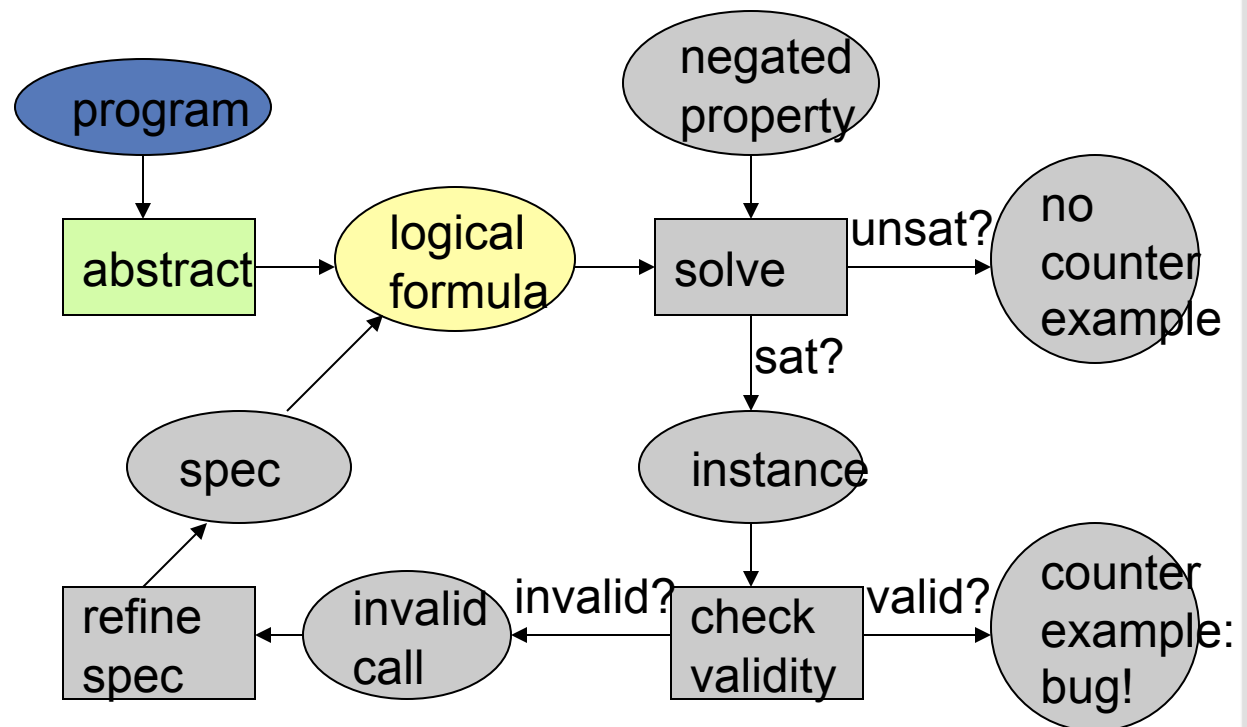

spec: CallStmt  $\times$  VarMap  $\times$  ValueMap  $\rightarrow$  Formula  $\times$  VarMap

- Overapproximates the effects of a call site

# Framework: abstraction

```

procedure p() {
  stmt1;
  q(); spec(q)
  stmt2;
}
  
```

- Translates all statements but call sites
- Replaces call sites with their specs
  - Empty specs
  - Frame condition
  - Richer specs

## Example – relational view

Relational view of the heap:

- Types: sets
- Fields: binary functional relations
- Variables: singleton sets

```
class JobList {  
  Entry head; }  
  
class Entry {  
  Job job;  
  Entry next; }  
  
class Job {  
  JobList predecessors;  
  JobList successors;  
  int predsNum;  
  int succsNum;  
  int visitedPredsNum; }
```

```
JobList, Entry, Job : set Obj  
head: JobList → Entry  
  
job: Entry → Job  
next: Entry → Entry  
  
predecessors: Job → JobList  
successors: Job → JobList  
predsNum: Job → Int  
succsNum: Job → Int  
visitedPredsNum: Job → Int
```

## Example – empty specs

```

Entry findReady(Entry e) {
  Entry c = e;
  while ((c != null) &&
         (c.job.predsNum != c.job.visitedPredsNum))
    c = c.next;
  return c;
}

```

```

void fixVisited(Job j) {
  Entry e = j.successors.head;
  while (e != null) {
    e.job.visitedPredsNum = e.job.visitedPredsNum + 1;
    e = e.next;
  }
}

```

```

return = ?Entry
job' = ?
next' = ?
head' = ?
predecessors' = ?
...

```

```

visitedPredsNum' = ?Job → ?Int
job' = ?
next' = ?
head' = ?
...

```

## Example – frame conditions

```
Entry findReady(Entry e) {  
  Entry c = e;  
  while ((c != null) &&  
         (c.job.predsNum != c.job.visitedPredsNum))  
    c = c.next;  
  return c;  
}
```

??

```
void fixVisited(Job j) {  
  Entry e = j.successors.head;  
  while (e != null) {  
    e.job.visitedPredsNum = e.job.visitedPredsNum + 1;  
    e = e.next;  
  }  
}
```

??

## Example – frame conditions

```

Entry findReady(Entry e) {
  Entry c = e;
  while ((c != null) &&
         (c.job.predsNum != c.job.visitedPredsNum))
    c = c.next;
  return c;
}

```

```

void fixVisited(Job j) {
  Entry e = j.successors.head;
  while (e != null) {
    e.job.visitedPredsNum = e.job.visitedPredsNum + 1;
    e = e.next;
  }
}

```

```

return = ?Entry
job' = job
next' = next
head' = head
predecessors' = predecessors
...

```

```

visitedPredsNum' = ?Job → ?Int
job' = job
next' = next
head' = head
...

```

# Example – abstraction

(l.jobs' = l.jobs)

```

boolean scheduleJobs(JobList l) {
  boolean isAcyclic = true;
  l.init();
  Entry cur = l.head;
  while (cur != null) {
    Entry ready = findReady(cur);
    if (ready == null) {
      isAcyclic = false; break; }
    fixVisited(ready.job);
    swapJobs(ready, cur);
    cur = cur.next;
  } return isAcyclic;
}

```

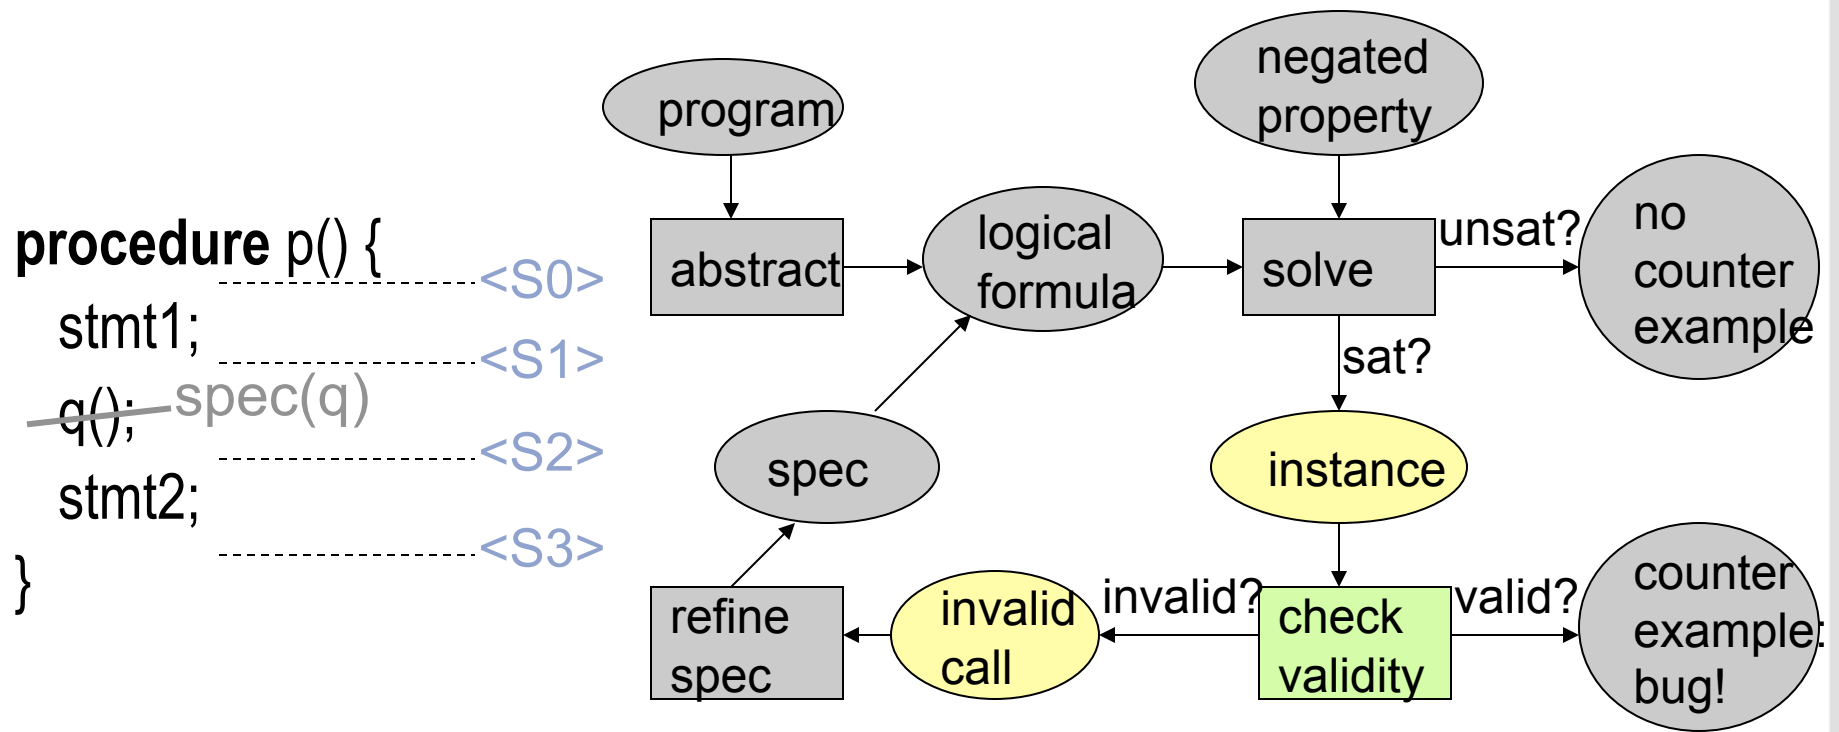

visitedPredsNum' = ?<sub>Job</sub> → ?<sub>Int</sub>

\$ret = ?<sub>Entry</sub>

visitedPredsNum' = ?<sub>Job</sub> → ?<sub>Int</sub>

job' = ?<sub>Entry</sub> → ?<sub>Job</sub>

# Framework: validity check

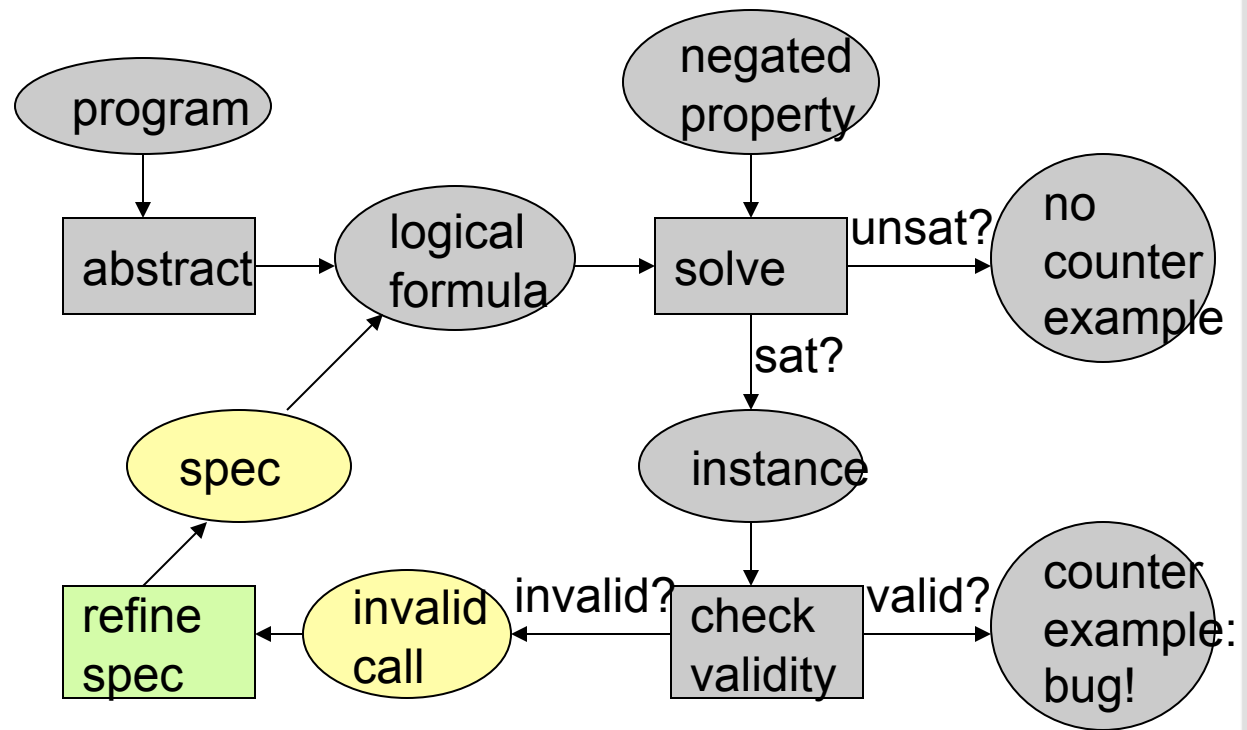

- Instance = trace in abstract program
- Examine each call: solve  
S1  $\wedge$  translate(q)  $\wedge$  S2
- If unsatisfiable, the call is invalid

# Framework: spec refinement

```

procedure p() {
  stmt1; ?
  q(); spec(q)
  stmt2;
}
  
```

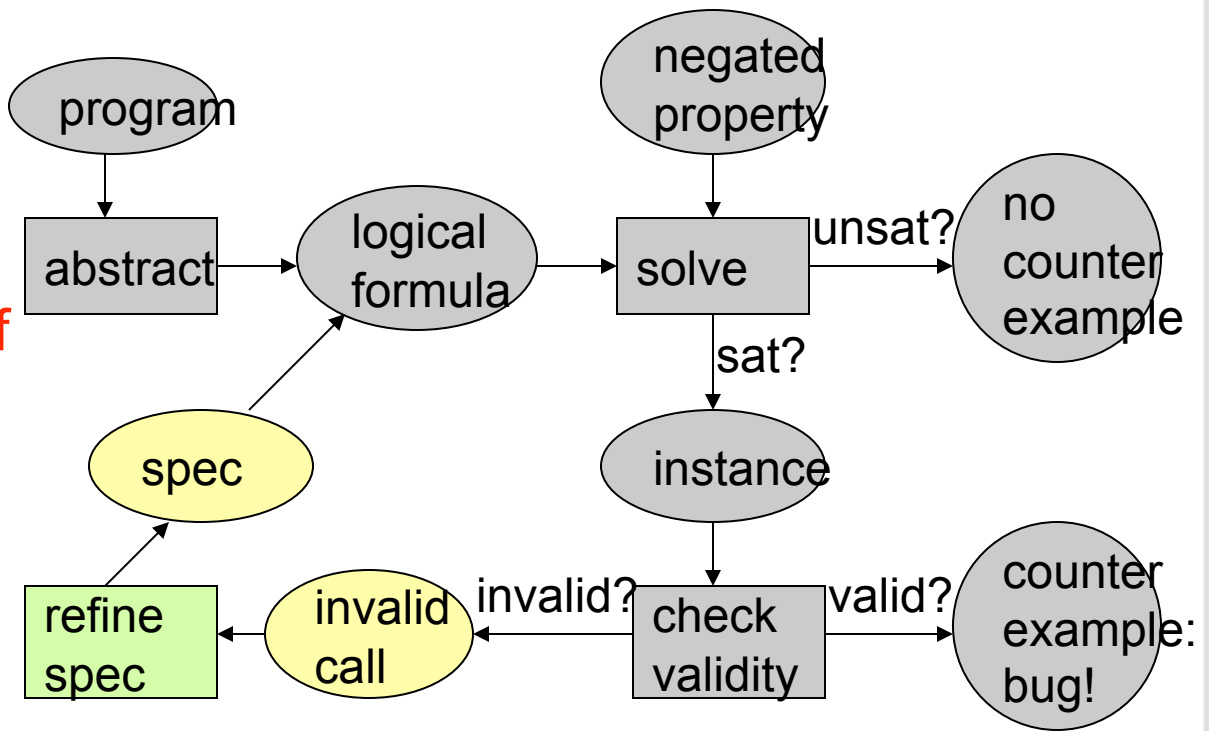

$preState(q) \wedge translate(q) \wedge postState(q) = false$

- New spec must eliminate  $(preState(q), postState(q))$
- $translate(q)$  can be the new spec
- **Too big!**

# Framework: spec refinement

```

procedure p() {
  stmt1; spec(q) ∧ proof
  q(); spec(q)
  stmt2;
}
  
```

$\text{preState}(q) \wedge \text{translate}(q) \wedge \text{postState}(q) = \text{false}$

▪ **Proof of unsatisfiability:**

An unsatisfiable consequence of the solved formula

$\text{translate}(q) \Rightarrow \text{proof}$

$\text{preState}(q) \wedge \text{proof} \wedge \text{postState}(q) = \text{false}$

# Example – spec refinement

(l.jobs' = l.jobs)

```

boolean scheduleJobs(JobList l) {
  boolean isAcyclic = true;
  l.init();
  Entry cur = l.head;
  while (cur != null) {
    Entry ready = findReady(cur);
    if (ready == null) {
      isAcyclic = false; break; }
    fixVisited(ready.job);
    swapJobs(ready, cur);
    cur = cur.next;
  } return isAcyclic;
}

```

(cur = E0)  
 (E0.job = J0) (E0.next = null)  
 ...

Pre-state

(ready = E1)  
 (E1.job = J1) (E1.next = null)  
 ...

Post-state

Why is this a possible instance???

# Spec refinement – example

```

Entry findReady(Entry e) {
  Entry c = e;
  while ((c != null) &&
    (c.job.predsNum != c.job.visitedPredsNum))
    c = c.next;
  return c;
}
  
```

Pre-state

(e = E0)  
 (E0.job = J0) (E0.next = null)  
 ...

Post-state

(\$ret = E1)  
 (E1.job = J1) (E1.next = null)  
 ...

Translation of findReady  
 (one unrolling)

$(e = \text{null}) \Rightarrow (\$ret = e)$   
 $((e \neq \text{null}) \wedge (e.\text{job.predsNum} = e.\text{job.visitedPredsNum})) \Rightarrow (\$ret = e)$   
 $((e \neq \text{null}) \wedge (e.\text{job.predsNum} \neq e.\text{job.visitedPredsNum})) \Rightarrow (\$ret = e.\text{next})$   
 $(e.\text{next} = \text{null})$

# Spec refinement – example

```

Entry findReady(Entry e) {
  Entry c = e;
  while ((c != null) &&
    (c.job.predsNum != c.job.visitedPredsNum))
    c = c.next;
  return c;
}
  
```

Pre-state

(e = E0)  
 (E0.job = J0) (E0.next = null)  
 ...

Post-state

(\$ret = E1)  
 (E1.job = J1) (E1.next = null)  
 ...

Translation of findReady  
 (one unrolling)

$(e = \text{null}) \Rightarrow (\$ret = e)$   
 $((e \neq \text{null}) \wedge (e.\text{job.predsNum} = e.\text{job.visitedPredsNum})) \Rightarrow (\$ret = e)$   
 $((e \neq \text{null}) \wedge (e.\text{job.predsNum} \neq e.\text{job.visitedPredsNum})) \Rightarrow (\$ret = e.\text{next})$   
 $(e.\text{next} = \text{null})$

false

# Spec refinement – example

```

Entry findReady(Entry e) {
  Entry c = e;
  while ((c != null) &&
    (c.job.predsNum != c.job.visitedPredsNum))
    c = c.next;
  return c;
}

```

Pre-state

(e = E0)  
 (E0.job = J0) (E0.next = null)  
 ...

Post-state

(\$ret = E1)  
 (E1.job = J1) (E1.next = null)  
 ...

Translation of findReady  
 (one unrolling)

(e = null)  $\Rightarrow$  (\$ret = e)  
 ((e != null)  $\wedge$  (e.job.predsNum = e.job.visitedPredsNum))  
 $\Rightarrow$  (\$ret = e)  
 ((e != null)  $\wedge$  (e.job.predsNum != e.job.visitedPredsNum))  
 $\Rightarrow$  (\$ret = e.next)  
 (e.next = null)

# Spec refinement – example

```

Entry findReady(Entry e) {
  Entry c = e;
  while ((c != null) &&
    (c.job.predsNum != c.job.visitedPredsNum))
    c = c.next;
  return c;
}
  
```

Pre-state

(e = E0)  
 (E0.job = J0) (E0.next = null)  
 ...

Post-state

(\$ret = E1)  
 (E1.job = J1) (E1.next = null)  
 ...

Translation of findReady  
 (one unrolling)

(e = null)  $\Rightarrow$  (\$ret = e)  
 ((e != null)  $\wedge$  (e.job.predsNum = e.job.visitedPredsNum))  
 $\Rightarrow$  (\$ret = e)  
 ((e != null)  $\wedge$  (e.job.predsNum != e.job.visitedPredsNum))  
 $\Rightarrow$  (\$ret = e.next)  
 (e.next = null)

New spec:  
 (\$ret = e) || (\$ret = e.next)

# Spec refinement

- What is a good spec to start with?
  - Are frame conditions good enough?
- What is a good pace to make progress?
  - Is proof of unsatisfiability good enough?

# Spec refinement

- Other ideas for 'invalidate'?
  - $\text{Translate}(q)$  and  $S$  and  $S' = \text{False}$

# Spec refinement: pace of progress

pre-state (s)

procedure q(..) {

.  
.  
.

}

post-state (s')

case-based:

$\neg( s \wedge s' )$

• good or bad?

# Spec refinement: pace of progress

pre-state (s)

procedure q(..) {

.  
.  
.

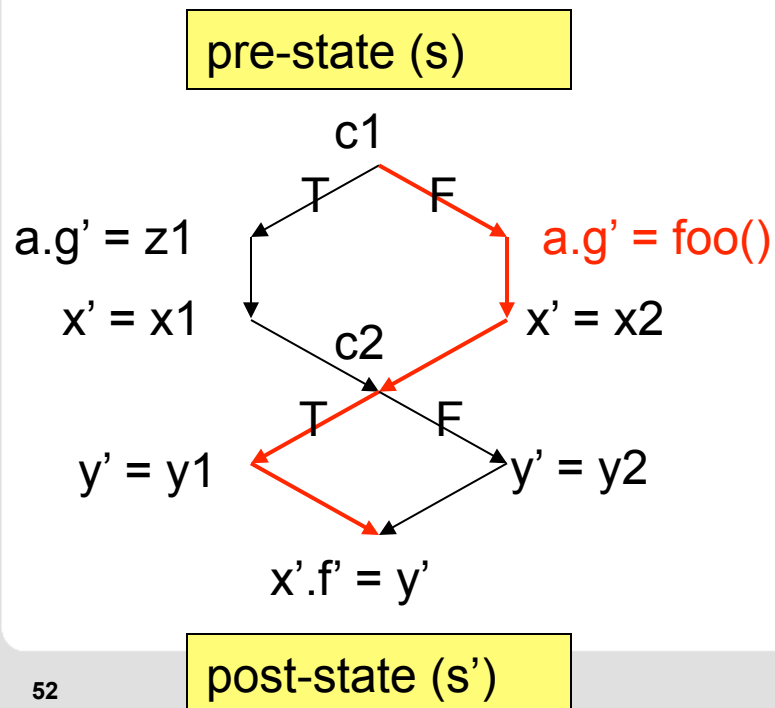

}

post-state (s')

case-based:  
 $\neg( s \wedge s' )$

- number of refinements proportional to the number of states allowed

# Spec refinement: pace of progress

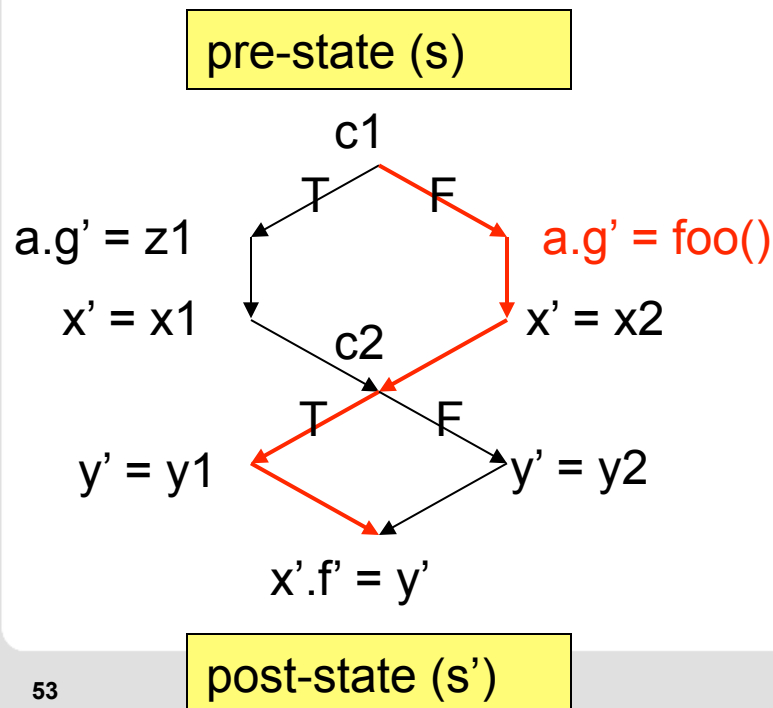

exec path:

$$(\neg c1 \wedge c2) \Rightarrow f' = f ++ x2 \rightarrow y1 \wedge$$

$$g' = g ++ a \rightarrow \text{foo\_ret}$$

• pros / cons?

# Spec refinement: pace of progress

exec path:

$$(\neg c1 \wedge c2) \Rightarrow f' = f ++ x2 \rightarrow y1 \wedge$$

$$g' = g ++ a \rightarrow \text{foo\_ret}$$

- number of refinements proportional to the number of paths
- refined spec may be unnecessarily complex

# Spec refinement: pace of progress

pre-state (s)

post-state (s')

unsat proof:

$$c2 \Rightarrow f' = (f ++ x1 \rightarrow y1) \parallel$$

$$f' = (f ++ x2 \rightarrow y1)$$

- extracts only relevant pieces
- may encode more than one path
- checks an abstraction of code:  
inner calls still abstract

## Initial specifications

### Affects performance

- Better specs reduce number of refinements
- Time spent to get rich specs may be wasted

### Lightweight technique:

- Specifies upper and lower bounds on final values

$$\text{relational expr} \subseteq \text{field'/'variable'} \subseteq \text{relational expr}$$

- Results are sometimes precise

$$\text{field'/'variable'} = \text{relational expr}$$

## Example – relational specs

```
Entry findReady(Entry e) {  
  Entry c = e;  
  while ((c != null) &&  
         (c.job.predsNum != c.job.visitedPredsNum))  
    c = c.next;  
  return c;  
}
```

$$\text{\$ret} \subseteq (e.\text{next} \ \& \ (\text{null} + \text{job.predsNum}.\text{(e.\text{next}.\text{job.visitedPredsNum}))})$$
$$\text{\$ret} \supseteq \emptyset$$

## Experiments – Quartz API

- Open source library for job scheduling
  - Used by “thousands of people”
  - Uses several data structures (e.g. list, map, set, ordered set)
- Checked 40 Methods in 4 Units
  - Containing up to 53 distinct called methods
- Checked correctness properties
  - Extracted from comments
  - Written as partial specs
- Found two previously unknown bugs

# 1<sup>st</sup> bug found in Quartz

- The bug:
  - In a called procedure (a very basic one)
  - Observable by users of Quartz
- This particular post-condition was never tested by developers
- The code:
  - Contains 17 method calls
  - Accesses 4 different maps and 2 ordered sets
